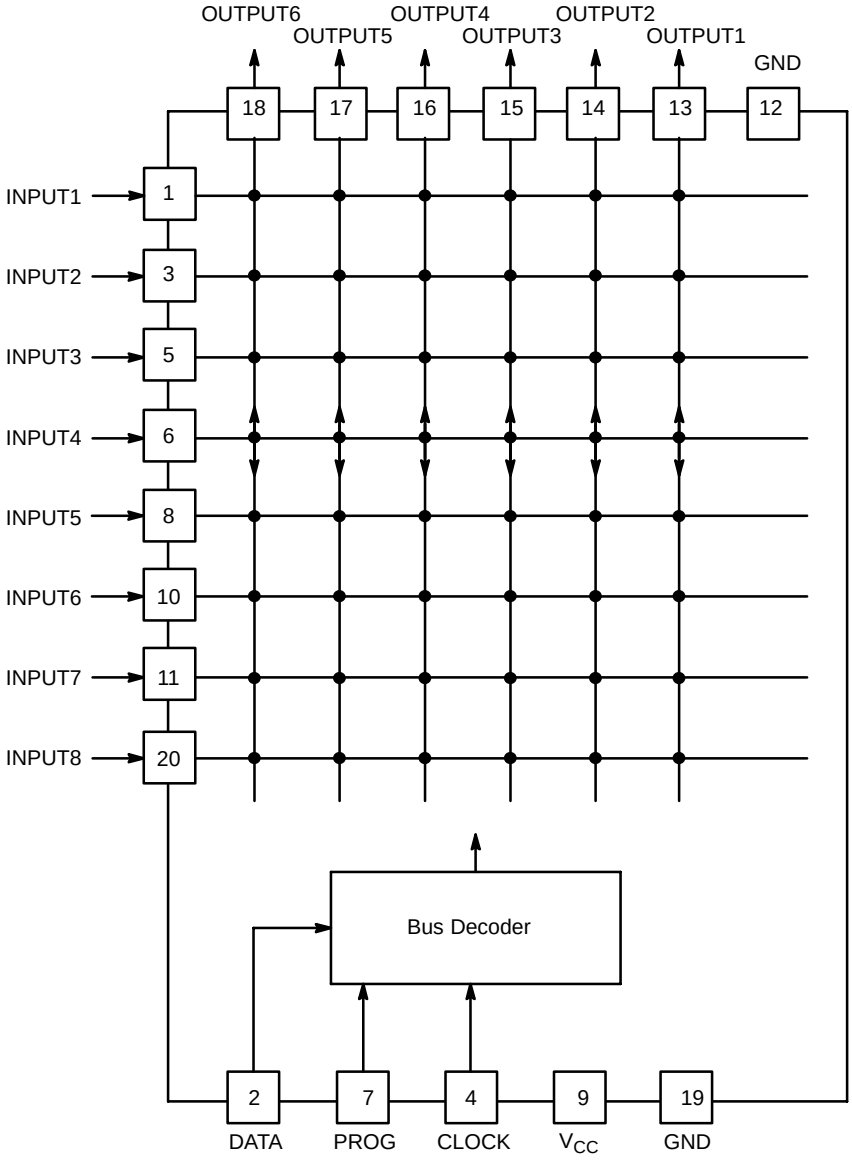

Figure 1. Block Diagram

The main function of the NCS6415 is to switch 8 video input sources to the 6 outputs.

Each output can be switched to only one of the inputs, whereas any single input may be connected to several outputs. The lowest level of each signal is aligned on each input (bottom of sync pulse for CVBS or Black Level for RGB signals).

The nominal gain between any input and output is 6 dB. For Chroma signals, the alignment is switched off by forcing, with an external 5‘ VDC resistor bridge on the input. Each input can be used as a normal input or as a Chroma input (with external resistor bridge). All the switching possibilities are changed through the I^2C bus.

The switches configuration is defined by words of 16 bits: one word of 16 bits for each output channel.

So, 6 words of 16 bits are necessary to determine the starting configuration upon power−on (power supply: 0 to 10 V). But a new configuration needs only the words of the changed output channels. Driving a 75 Ω load requires an external transistor.

USING A SECOND NCS6415

The programming input pin (PROG) allows two NCS6415 circuits to operate in parallel and to select them independently through the I^2C bus by modifying the address byte. Consequently, the switching capabilities are doubled, or IC1 and IC2 can be cascaded (see Figure 7).

TYPICAL APPLICATION DIAGRAM

NCS6415 is suited for single supply system, running on a single +10 V supply. The high quality of the output stage and excellent linearity provides video signal comparable to broadcast studio quality signals. The layout is not as critical to the design and it can be easily realized on a single sided board.
